# 01

**Deliverables  
Introduction &  
Overview**

The development, packaging, and submittal of Digital Deliverable files helps facilitate the handoff between design and construction phases of projects. This process allows these files to be used during construction to automate, and simplify, construction methodology so that native design files can be used to construct the proposed elements. This can help improve quality, reduce construction time, and reduce requests for information.

Use cases for the data are listed in the table below with an emphasis on Automated Machine Guidance (AMG), construction model building, Civil Engineering Inspection, and integration with other field equipment and workflows.

**Types of NCDOT Digital Deliverables:**

Digital Deliverable	File Name & Format	Description	Purpose
Alignments & Profiles	TIP#_CREG_ALG.xml (LandXML)	All existing and proposed controlling horizontal alignments and vertical profiles referenced in design files and plan sheets.	Input into various construction and survey equipment for reference and verification.
Final Grade Top Surface	TIP#_CREG_TFG.xml (LandXML)	Triangulated surface developed from proposed modeled elements that captures project improvements and modifications.	Can be loaded into survey equipment and construction equipment for verification of built conditions, as well as being used for AMG workflows.
Final Subgrade Surface	TIP#_CREG_FSG.xml (LandXML)	Triangulated surface developed from roadway models depicting the surface at the subgrade level of the roadway improvements.	Can be used with AMG equipment, or to verify site conditions when preparing subgrade.
Existing Top Surface	TIP#_CREG_ETM.xml (LandXML)	Triangulated surface provided by the project surveyor which also incorporates any update survey received throughout the project design process depicting the existing ground surface.	Captures all survey of existing surfaces to provide as reference and for verification.
3D Breaklines	TIP#_CREG_BRK (.dxf)	3D linestrings generated by the proposed project model which represents the breaklines of the proposed project elements.	Can be loaded as a native file format into many construction and survey software suites.
2D Planimetrics	TIP#_CREG_PLN (.dxf)	2D planimetric representation of the design for use in construction software and field equipment	Can be used in junction with 3D surface for rovers and AMG workflows or for GIS integration.

**Note:** IFC file exports to be added at a later date

These Digital Deliverables files may or may not be construction contract documents. Refer to the NCDOT CADD Manual for submittal requirements and policy.

NCDOT has adopted CADD (.dgn) and LandXML formats as the standard for delivery for Digital Deliverables, including AMG files. LandXML includes basic geometry element types, and can be used by many software platforms used in the construction industry including AGTEK, Trimble, Carlson, and others.

# 02

## Alignments and Profiles

Alignments and profiles are exported to LandXML files and represent the controlling geometry of projects. These may include existing and proposal alignments / profiles, depending on what is available on the project. Any proposed project elements, or project data, that references an existing alignment would require the existing alignment (i.e. BL Survey) be included in the export as well.

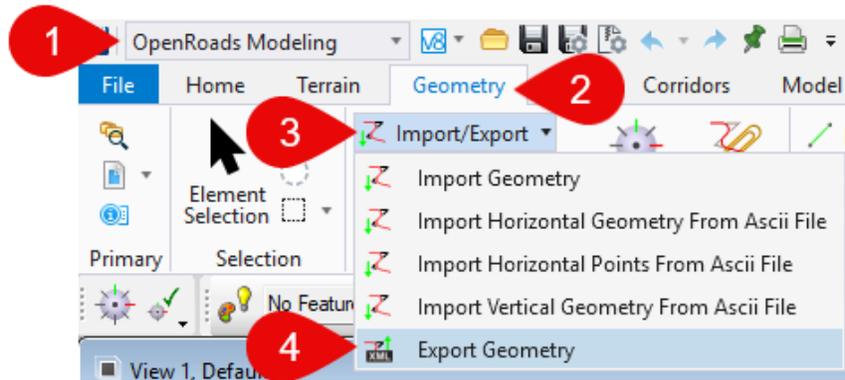

## Preparation & Review Best Practices

1. Review the following items in each .dgn file prior to exporting alignments and profiles:
  - Geographic Coordinate System is set for 2D and 3D models
  - Verification unit settings are correct and file names match CAD manual requirements
  - Alignments have the correct profiles set as active; if multiple profiles are applicable to a single alignment (i.e. LT/RT PGL) then take note to ensure to export all profiles for that alignment, not just “active” profile and cleanup any working linework or profile scratch linework, so they don’t export
2. Compress files prior to exporting; fit view to ensure no elements floating off in space

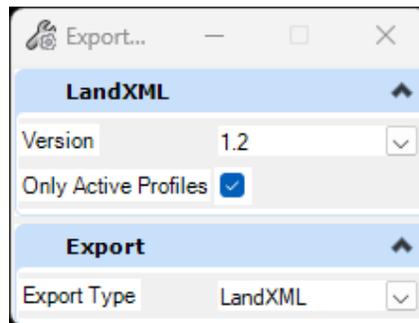

Continued next page →

## Exporting of Files

1. Export each alignment using the following workflow:
  - With the alignment file open, switch to the Default Model (2D) view
  - Navigate to:
    - Geometry > General Tools > Import/Export > Export Geometry

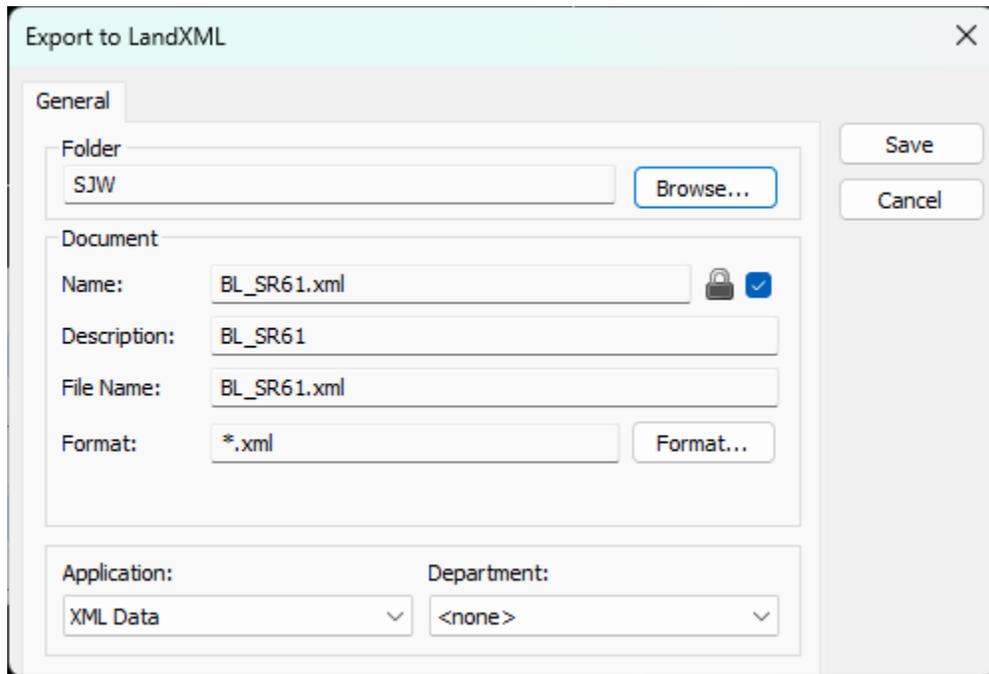

- In the Export Geometry dialog:
  - Export Format: Select **LandXML**
  - Select the alignment
  - Version: Choose 1.2
  - Include Profiles: Check export *Only Active Profiles*

**Note:** If multiple profiles are associated with a single alignment and you wish for all of them to be exported at once, uncheck this box to capture all profiles.

Continued next page →

- The Export to LandXML dialogue opens
  - Select No Wizard (if using ProjectWise)
  - Navigate to the appropriate export folder
  - Enter the LandXML file name
  - Verify that LandXML (.xml) is the **Save as** type
  - Click **Save**

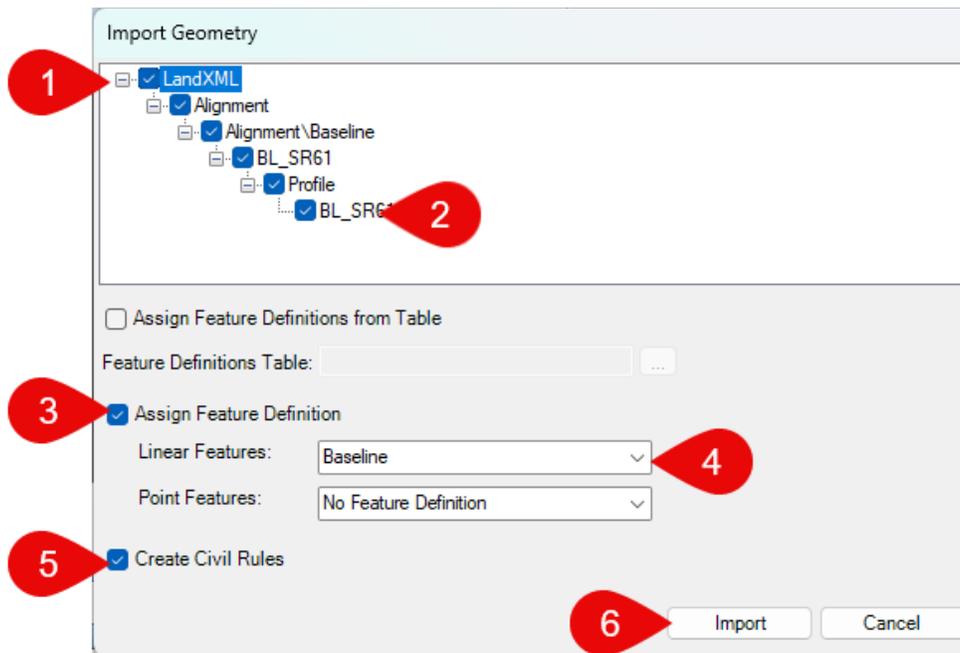

- Save the file in the project folder
- Repeat the above steps for each alignment in the file

## Review of Exported Files

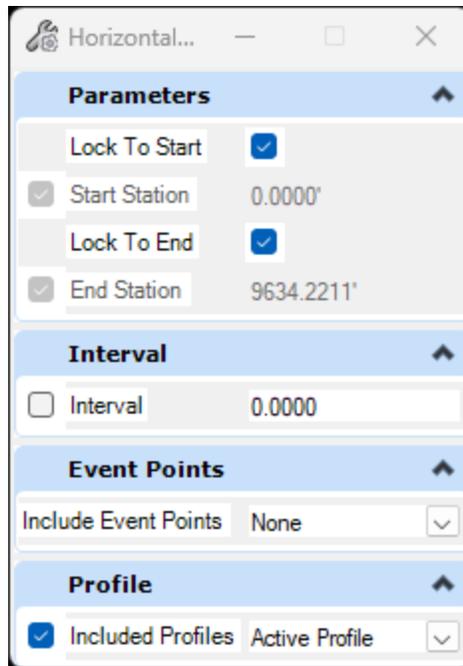

Each Digital Deliverable (.xml) file shall be reviewed to ensure all data exported correctly. While third-party construction and survey software can be used to review the exported files, it is recommended to utilize OpenRoads Designer:

1. Create and open up a new (blank) .dgn file from the NCDOT 2D seed
  - Import the alignment LandXML (.xml) file
  - Navigate to:
    - Geometry > General Tools > Import/Export > Import Geometry
  - Navigate to the .xml file, and click **Open**
    - Expand the Alignment selection and expand down to the appropriate profile. Check the box next to the profile.
    - Check the **box** to *Assign Feature Definition*
    - Select the appropriate *Linear Feature Definition*
    - Check the **box** to *Create Civil Rules*
    - Click *Import*

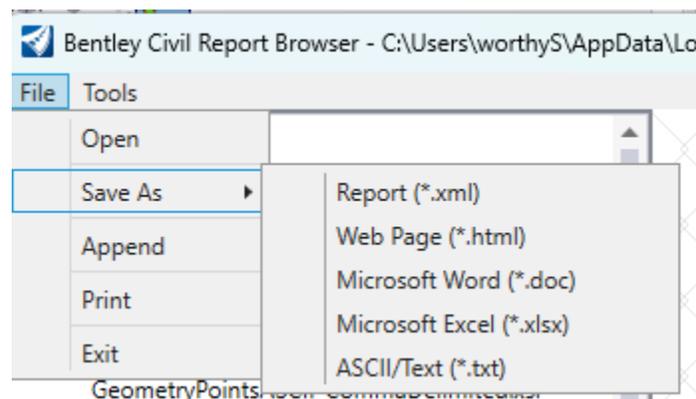

2. Generate the Horizontal Geometry Report for the imported alignment and Vertical Geometry Report for the imported profile, and compare to the original design file(s).

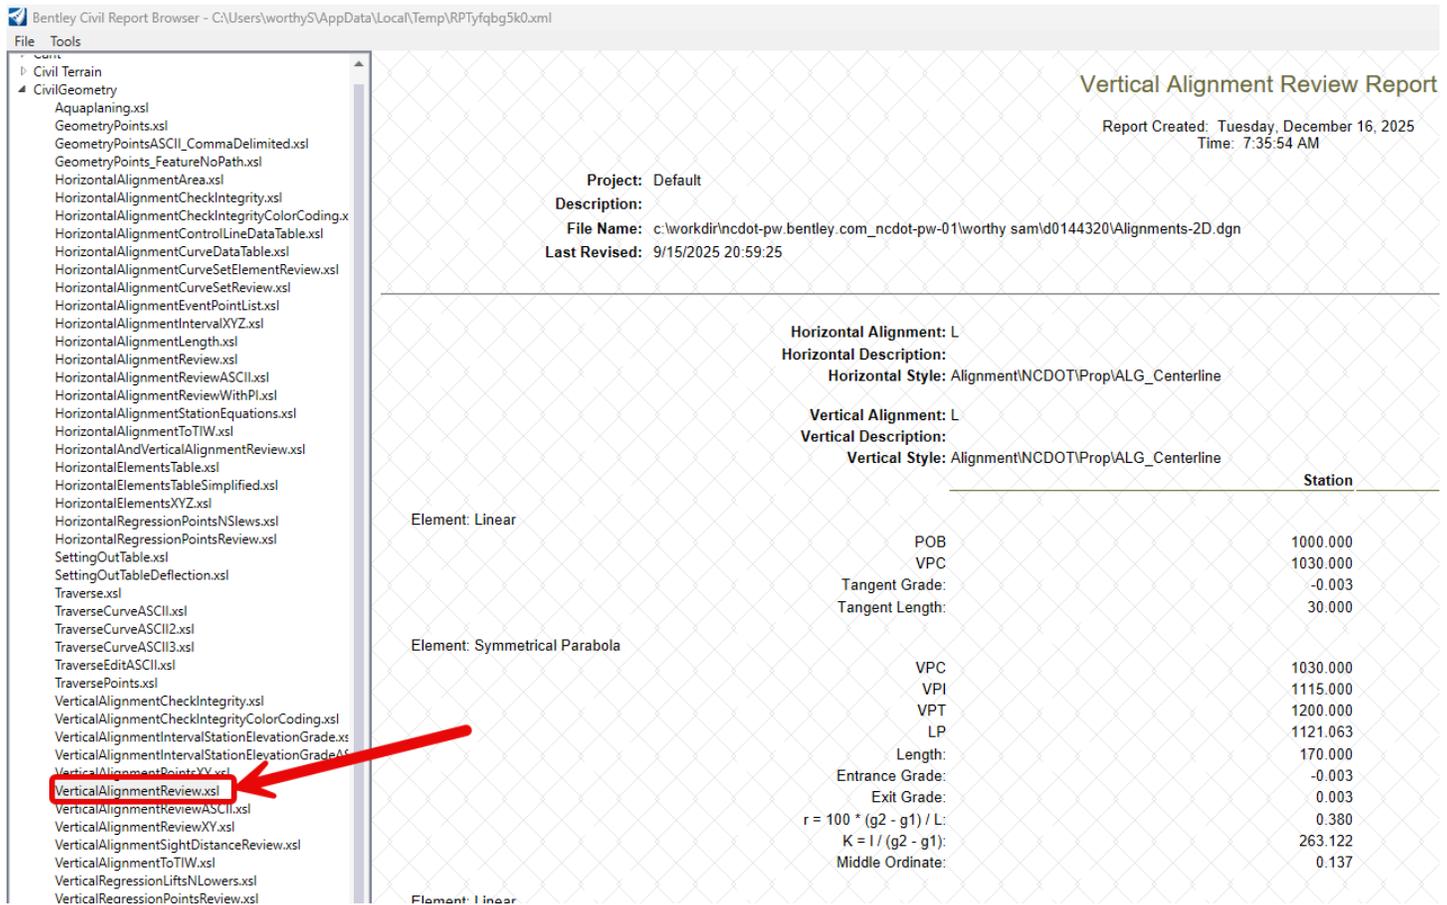

- Navigate to:
  - Geometry > General Tools > Import/Export > Horizontal Geometry Report
- Click on the alignment
- Toggle on **Lock to Start** and **Lock to End**
- Toggle on **Include Profiles** (set to **Active Profile**)

- The Horizontal Report dialogue will appear, with the default horizontal geometry report. This report can be printed to PDF, or saved as an Excel file:

3. Once complete, click on VerticalAlignmentReview.xml in the navigation bar on the left, this will load the vertical report for the active profile:

**Vertical Alignment Review Report**  
 Report Created: Tuesday, December 16, 2025  
 Time: 7:35:54 AM

**Project:** Default  
**Description:**  
**File Name:** c:\workdir\ncdot-pw.bentley.com\_ncdot-pw-01\worthy sam\d0144320\Alignments-2D.dgn  
**Last Revised:** 9/15/2025 20:59:25

---

**Horizontal Alignment:** L  
**Horizontal Description:**  
**Horizontal Style:** Alignment\NCDOT\Prop\ALG\_Centerline

**Vertical Alignment:** L  
**Vertical Description:**  
**Vertical Style:** Alignment\NCDOT\Prop\ALG\_Centerline

	Station
Element: Linear	
POB	1000.000
VPC	1030.000
Tangent Grade:	-0.003
Tangent Length:	30.000
Element: Symmetrical Parabola	
VPC	1030.000
VPI	1115.000
VPT	1200.000
LP	1121.063
Length:	170.000
Entrance Grade:	-0.003
Exit Grade:	0.003
$r = 100 * (g2 - g1) / L:$	0.380
$K = 1 / (g2 - g1):$	263.122
Middle Ordinate:	0.137

- Save the vertical report locally
- Navigate back to the project alignment file (.dgn) and repeat the same steps for the original alignment and profile, and compare the reports to ensure the data matches.

# 03

## Surfaces

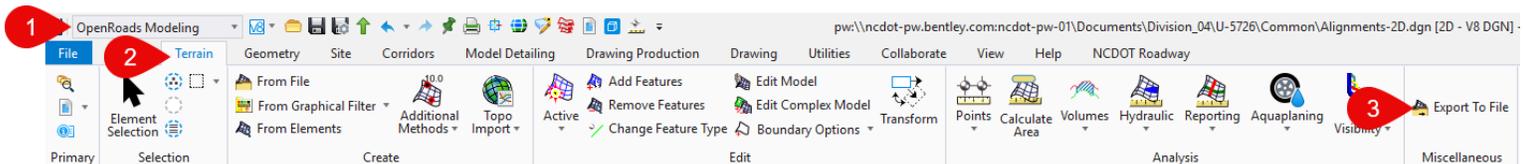

There are three types of surfaces that are exported as part of the Digital Deliverables; existing top grade, proposed top grade, and proposed subgrade. These surfaces are exported to LandXML files and represent the existing and proposed top surfaces, and the subgrade that will be constructed as part of any roadway improvements. Surfaces may be broken up in order to maintain LandXML files of less than 500mb in size as a best practice.

## Preparation & Review Best Practices

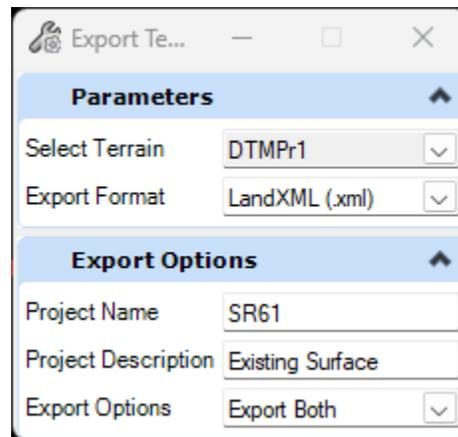

- 1) Review the following items in each .dgn file prior to exporting surfaces:
  - Geographic Coordinate System is set for 2D and 3D models
  - Verify no visual gaps, spikes, lips, or overlapping areas exist within the surfaces
  - Proposed surfaces (top and subgrade) are up to date and take into account all necessary proposed components
  - Proposed top surface ties to existing surface without any gaps, voids, etc.
- 2) Best Practice - There are two considerations to take into account when developing proposed top surfaces
  - Vertical Faces – triangulated terrains cannot resolve between two points that share the same xy values, but at different elevations. As a result, exactly vertical faces cannot be present in a triangulated surface. As a result, all model components used for surface creation must have a horizontal offset value no less than 0.01 feet.
  - Caves and Cliffs – When generating subgrade surfaces, the triangulation cannot double back on itself and create overlapping areas (i.e. extend over a component then wrap around either above or below other triangles). As a result, all components, points, and breaklines used to generate surfaces must be setup to avoid these situations.

## Exporting of Files

1. Export the **existing surface** using the following workflow:
  - Navigate to the survey file with the project's existing surface / terrain
  - Verify the number of existing terrains (if more than one)
  - Navigate to:
    - OpenRoads Modeling > Terrain > Miscellaneous > Export to File

- Select the terrain
- Select the *Export Format*: **LandXML**
- Enter the *Project Name*
- Enter the *Project Description*: **Existing Surface**
- Select the *Export Options*: **Both**

- Save the file in the project folder
2. Create and Export Final Surface Files: Final Grade Top Surface & Final Subgrade Surface
- **Surface Creation Option 1 – Graphical Filter**
    - In a clean design file, reference in proposed modeling files
    - Open the Terrain Filter Manager
    - Setup, or use an existing, graphical filter to define model breaklines to include
      - Note: Separate filters can be developed and combined into a Filter Group to easily apply all filters at once
    - Open the Create Terrain by Graphical Filter tool
    - Specify the Filter, or Filter Group, to apply
    - Specify the edge method to be used
      - Best Practice – specify Max Triangle Length for the method, with a value of 25
    - Set the Feature Definition to the appropriate terrain feature definition
    - Provide the appropriate terrain name
    - Click through the options to generate the terrain
  - **Considerations** with Surface Creation Option 1 - Graphical Filter method:
    - Changes to the reference models will not automatically update terrains created using this method. Updates can be captured by re-opening the file with the live terrain, Opening the Project Explorer, navigating to the terrain, right-clicking and choosing “Update Terrain Source”
    - This methodology requires careful setup and review of references linestrings/breaklines to be used for the generation of the terrain
    - Careful review of the terrain(s) compared to the proposed model should occur to ensure all necessary components were taken into account
  - **Surface Creation Option 2 – From Breaklines**  
(Follow the steps outlined in Section 4 of this document, or follow the abbreviated steps below)
    - Open up a new, clean, design (.dgn) file using the 3D design seed

- Reference in the proposed modeling files 3D model space which contain elements to be included in the surface. Do not include any 2D references or 3D cells.
- Set the Geographic Coordinate System of the file to match the reference
- Turn off all unnecessary construction lines, working lines, and surfaces that are not intended to be included in the surface
- Use the “Merge into Master” tool in the Reference Manager to merge all 3D breaklines (linear feature lines) into the file
- Delete 3D mesh elements, leaving only the 3D linestrings
- Any linestrings from surface templates will require manual offsetting of linework for linestrings at the edges of components (i.e. top of pavement and bottom of pavement) to avoid a vertical face between these linestrings which won’t triangulate
- Manually clean up gaps or overlaps in the merged linework; reference in and compare to model files to ensure consistency between the files
- Use the *Create Terrain Model from Elements* tool and select all breaklines (3D linestrings)
- Select the *feature* option of “**Break Line**”, and set the *Edge Option* to **Max Triangle Length** starting with a value of **25** and refining as needed afterwards (larger value may be needed)
- **Considerations** with Surface Creation Option 2 – From Breaklines method:
  - This method may still require cleanup of breaklines prior to surface/terrain creation
  - This method is *less dynamic* than other methods as breaklines are merged/copied into the file, so any further model updates will not be taken into account, and the workflow must be repeated.
  - Ensure the feature definitions for the modeled components are set to “**Enable Linear Features**” when placed. This results in 3D linestrings being generated in 3D model space to form breaklines.

Continued next page →

- **Surface Creation Option 3 – From Meshes**

- Open the modeling files with roadway corridor models live
- Modify the applied corridor feature definition properties to toggle Top Mesh Display (or Bottom Mesh Display) to **True**
- Use the *Create Terrain Model from Elements* tool and select all mesh elements

Select the *feature* option of **“Break Line”**, and set the *Edge Option* to **Max Triangle Length** starting with a value of **25** and refining as needed afterwards (larger value may be needed)

- **Considerations** with Surface Creation Option 3 – From Meshes method:

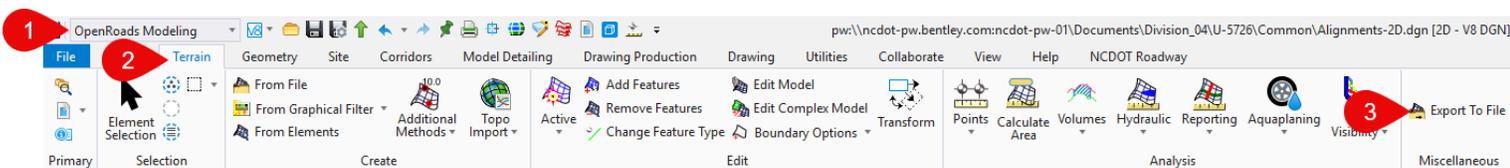

- This method requires detailed management of corridor template properties to ensure the correct components are included in top and bottom meshes.
- This method is somewhat dynamic, as terrains created from meshes generated by corridors will update once the original meshes used to create the terrains update (if the rules to the original meshes are still intact)
- Areas outside of corridors, without top/bottom mesh, must still be manually selected to be included (i.e. slopes, surface templates, etc.)

3. Review Terrains Prior to Export

- Review terrains for any gaps, spikes or errors
- Remove any extra triangles around any interior curves or features
- Utilize the Report Crossing Features and Report Conflicting Points tools to check the terrains for errors
- Update source information and recreate terrains if any issues are found

4. Exporting Terrains

- Navigate to:
  - OpenRoads Modeling > Terrain > Miscellaneous > Export to File

- Select the terrain
- Select the *Export Format*: **LandXML**
- Enter the *Project Name*
- Enter the *Project Description*: **Final Grade Top Surface** (or: **Final Subgrade Surface**)
- Select the *Export Options*: **Both**
- Click through the options, save the .xml file(s) in the appropriate project folder

## Review of Exported Files

Review of exported LandXML (.xml) surfaces is the same for all surface types.

- Create a new, clean, file using the 3D seed

- Set the Geographic Coordinate System
- Create (Import) a terrain from the LandXML (.xml) surface using the **Terrain > Create > From File** tool
- Review the terrain visually for any spikes, gaps, or other errors
- Run the Report Crossing Features and Report Conflicting Points analysis tools

# 04

## Final Grade Breaklines

The development of 3D model breaklines helps facilitate the generation and importing of design surfaces and information into construction and survey applications. Only top, proposed, surface breaklines should be included in this file.

## Preparation & Review Best Practices

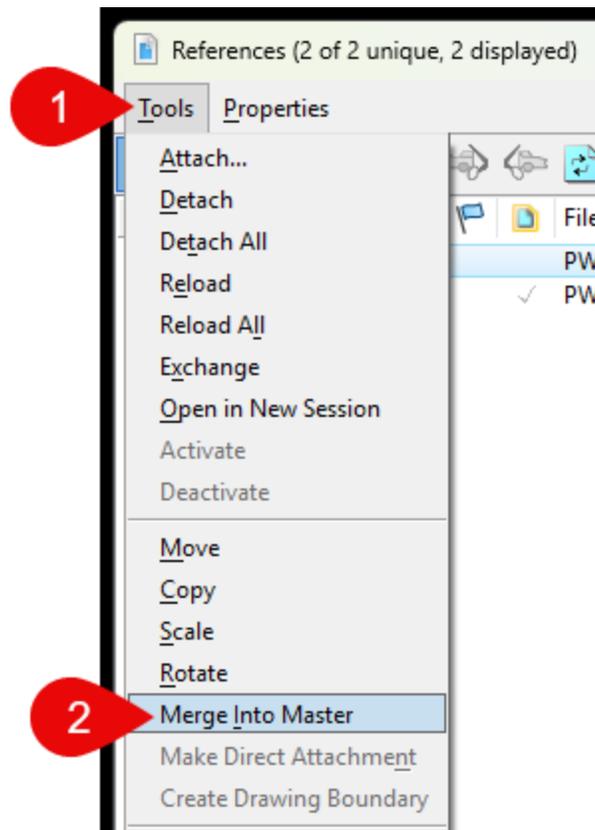

1. Review the following items in each .dgn file prior to generating and exporting breaklines:
  - Geographic Coordinate System is set for 2D and 3D models
  - Verify no visual gaps, spikes, lips, or overlapping areas exist within the model
  - Proposed corridors are up to date and take into account all necessary proposed components
  - Proposed model ties to existing surface without any gaps, voids, etc.
2. Best Practice - These are some considerations to take into account when developing proposed top surfaces
  - Level naming and feature definitions should be consistent for the same types of elements from model breaklines
  - Names should be unique between the different layers of material
  - If the model contains surface templates, then ensure feature definitions are set to “**Enable Linear Features**” when placed.
  - Ensure linear template feature definitions are set to Final
  - Utilize point and component feature name overrides to reduce, or eliminate gaps between different template drops along corridors

## Exporting of Files

1. Create a new Microstation (.dgn) file using the 3D design seed file (Note: this new file will only have a 3D design model in it, not a 2D design model)
2. Reference the 3D models of all proposed model files; do not include any 2D model information
3. Set the geographic coordinate system of the file to match the reference files
4. Filter / turn off all construction class lines and unnecessary linework, turn off anything that isn't a breakline (i.e. cells)

Continued next page →

- In the Reference Manager use the Merge into Master tool to copy all breaklines (3D linestrings) live into the file:

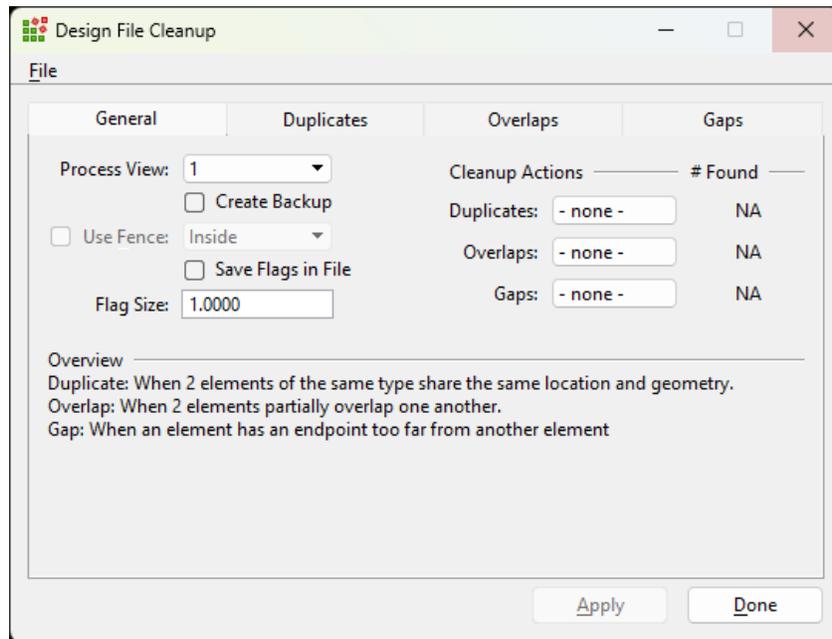

- Delete/remove any non-breakline elements that may have been copied in (i.e. 3D meshes, 2D linework, etc.)
- Select all 3D model breaklines and use the **OpenRoads Modeling > Drawing > Groups > Drop Complex Status** tool to simplify all breaklines.

Continued next page →

6. Review and cleanup the merged breaklines.

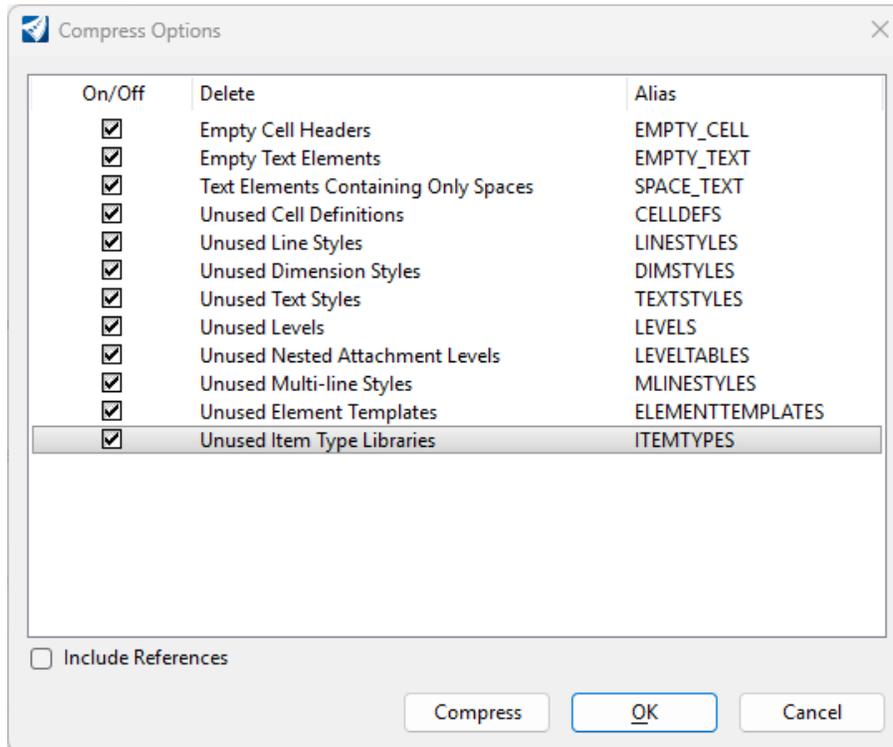

- Gaps or overlaps may occur and require a manual approach to 3D model breakline cleanup. The **Design File Cleanup** tool can be used to review and resolve gaps, overlaps, and duplicates:

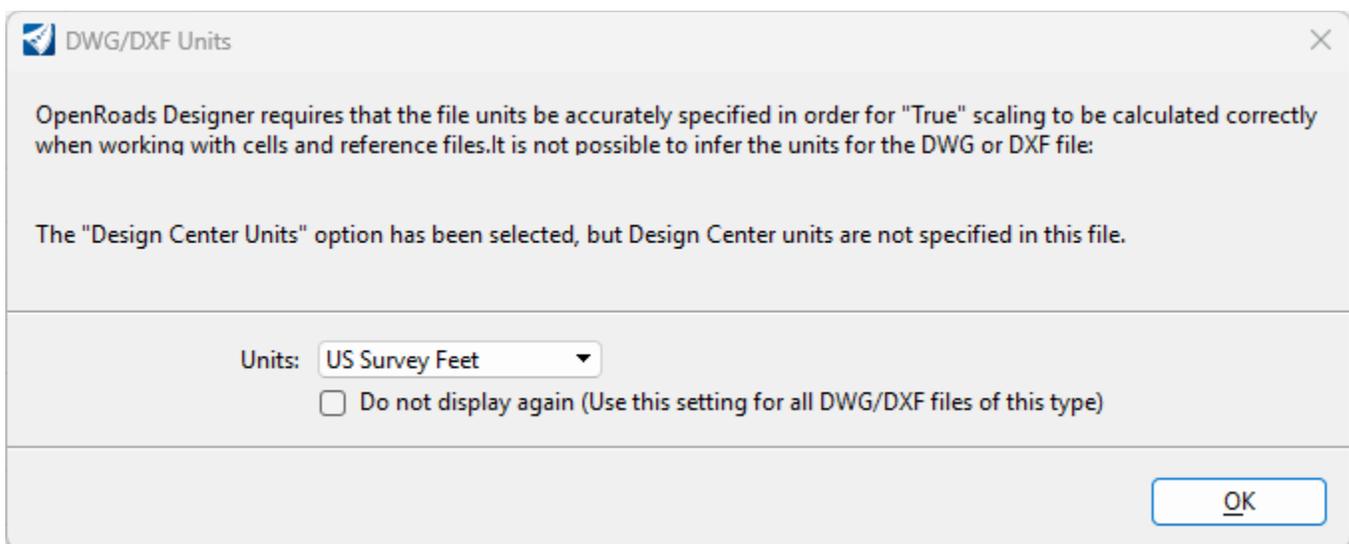

7. Review breaklines to identify any that would create a vertical face; since triangulation cannot occur in a vertical plane, any breaklines that directly overlap one another need to be offset by 0.01 ft to create a slight slope / delta between the breaklines to facilitate triangulation.

Continued next page →

8. Once cleaned up, compress the file by navigating to:
  - **File > Tools > Compress Options**
  - Turn on all options (except for Include References at the bottom) and click **Compress**

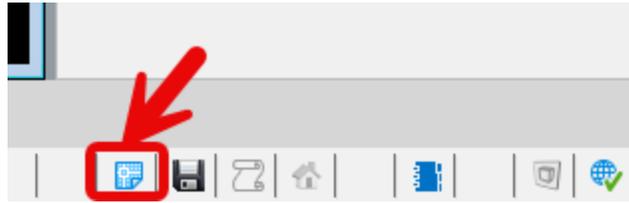

- Save the file
- Save an AutoCAD (.dxf) copy of the file by navigating to File > Save As
- Don't set any options, just provide a name and the correct location and click Save
- A dialogue pops up, select US Survey Feet and Click OK

## Review of Exported Files

Upon saving the .dwg file, OpenRoads Designer will open it in DWG Work Mode (indicated by the blue cross hair icon in the bottom right of the Microstation menu)

1. Reference in the 3D model file(s), compare the breaklines to the models and planimetric linework.
  - Identify any breaklines with gaps, overlaps, or duplicates and resolve as necessary.
  - All instances of the breaklines should matching including the 2D and 3D CREFs, DSN, CMD, XSC, and any other location in the plans.
