

You can create columns in your dataview, such as speed, using real numbers or as integers. However, the important thing to note is that if this column is then used in a calculation, your new field(column) has to be a real number if the other fields do not match in value type.

For example you can't have a length (real number) divided by speed(integer) and save the calculated value(travel time) as an integer in a new column. In order for travel time to be calculated correctly you must make travel time a real number before you do the calculation or you will get the error below.

To reference this to the conversation in the User's Group meeting, just make sure you create your travel time as a real number and you should be ok!!

**Simple Rule of thumb:** Make any column you create a real number if you will be filling by performing a calculation with another column that is a real number!
